How to choose a 12V power supply?

Part 4. Key parameters of a 12V power supply When selecting a 12V power supply, it's essential to consider several key parameters to ensure compatibility with your devices. Here are the most important ones to know:

Output Voltage: This should be 12V, but it's crucial to verify that it remains stable under various conditions.

Will a 12V 5A power supply work?

The power supply must be able to give enough amps. If your device usually uses a 12V 5A power supply, any power supply with 12V and 5 or more amps will work. If you use a power supply with less amps (2.5 instead of the required 3). The equipment might not work (but probably will), but you risk the chance of blowing up your power supply.

Can a 12V power supply blow up equipment?

Higher voltage = blow up equipment. Lower voltage = equipment will most likely not work properly (might cause damage on the long term). The power supply must be able to give enough amps. If your device usually uses a 12V 5A power supply, any power supply with 12V and 5 or more amps will work.

How many amps on a 12V PSU?

Amps on 12V are like wattage. Make sure it's enough then forget about it. There are much more important aspects in a PSU. Most decent power supplies can supply 100% of their power on their 12v rail anyway. Your system is fine with a good 500w+PSU /41+amps. So it's like a counts? And this ~55A total?

Which power supply should I use?

The other commenters have said that ideally you need a supply that has the spec'd voltage and which can supply at least the spec'd amount of current. One commenter has suggested trying the 12V, 2.5A supply and turning the brightness right down (which is probably your best bet). But that doesn't necessarily mean the other supplies won't work.

What do you need to know about a power supply?

Here are the most important ones to know: Output Voltage: This should be 12V, but it's crucial to verify that it remains stable under various conditions. Output Current (Amps): Determines the maximum load the power supply can handle without overheating. Power Rating (Watts): This is calculated by multiplying output voltage and current (12V $\times$ Amps).
